Python Programming Fundamentals Cheat Sheet

Package/Method	Description	Syntax and Code Example
AND	Returns 'True' if both statement1 and statement2 are 'True'. Otherwise, returns 'False'.	<pre>Example: marks = 90 attendance_percentage = 87 if marks >= 80 and attendance_percentage >= 85: print("qualify for honors") else: print("Not qualified for honors") # Output = qualify for honors</pre>
Class Definition	Defines a blueprint for creating objects and defining their attributes and behaviors.	<pre>Syntax: class ClassName: # Class attributes and methods Example: class Person: definit(self, name, age): self.name = name self.age = age</pre>
Define Function	A`function` is a reusable block of code that performs a specific task or set of tasks when called.	Syntax: def function_name(parameters): # Function body Example: def greet(name): print("Hello,", name)

about:blank 1/10

		Syntax:
		variable1 == variable2
		Example 1:
		5 == 5
Equal(==)	Checks if two values are equal.	
	·	
		returns True
		Example 2:
		age = 25
		age = 30
		returns False
For Loop	A 'for' loop repeatedly executes a block of code for a specified number of iterations or over a sequence of elements (list, range,	Syntax:
	string, etc.).	for variable in sequence: # Code to repeat
		Example 1:
		for num in range(1, 10): print(num)
		Francis 2
		Example 2:
		<pre>fruits = ["apple", "banana", "orange", "grape", "kiwi"] for fruit in fruits:</pre>
		print(fruit)
 hout:blank	ı	2/10

about:blank 2/10

Function Call	A function call is the act of executing the code within the function using the provided arguments.	Syntax: function_name(arguments) Example: greet("Alice")
Greater Than or Equal To(>=)	Checks if the value of variable l is greater than or equal to variable 2.	Syntax: variable1 >= variable2 Example 1: 5 >= 5 and 9 >= 5
		returns True Example 2: quantity = 105 minimum = 100 quantity >= minimum returns True
Greater Than(>)	Checks if the value of variable 1 is greater than variable 2.	Syntax: variable1 > variable2

```
Example 1: 9 > 6
                                                                                                                  returns True
                                                                                                                  Example 2:
                                                                                                                          age = 20
                                                                                                                         max_age = 25
age > max_age
                                                                                                                  returns False
                                                                                                                  Syntax:
                                                                                                                          if condition: #code block for if statement
If Statement
                               Executes code block 'if' the condition is 'True'.
                                                                                                                  Example:
                                                                                                                          if temperature > 30:
    print("It's a hot day!")
If-Elif-Else
                               Executes the first code block if condition1 is 'True', otherwise
                                                                                                                  Syntax:
                               checks condition2, and so on. If no condition is 'True', the else
                                                                                                                          if condition1:
                               block is executed.
                                                                                                                          # Code if condition1 is True
elif condition2:
                                                                                                                          \# Code if condition2 is True
                                                                                                                          else:
                                                                                                                          # Code if no condition is True
                                                                                                                  Example:
                                                                                                                         score = 85 # Example score
if score >= 90:
    print("You got an A!")
elif score >= 80:
    print("You got a B.")
else
                                                                                                                          print("You need to work harder.")
# Output = You got a B.
```

/13/25, 10:35 PM		about:blank
If-Else Statement	Executes the first code block if the condition is 'True', otherwise the second block.	<pre>Syntax: if condition: # Code, if condition is True else: # Code, if condition is False Example: if age >= 18: print("You're an adult.") else: print("You're not an adult yet.")</pre>
Less Than or Equal To(<=)	Checks if the value of variable1 is less than or equal to variable2.	Example 1: 5 <= 5 and 3 <= 5 returns True Example 2: size = 38 max_size = 40 size <= max_size

about:blank 5/10

9/13/25, 10:35 PM about:blank

```
Syntax:
                                                                                                           variable1 < variable2
                                                                                                    Example 1:
                                                                                                          4 < 6
Less Than(<)
                           Checks if the value of variable 1 is less than variable 2.
                                                                                                    returns True
                                                                                                    Example 2:
                                                                                                           score = 60
                                                                                                           passing_score = 65
score < passing_score
                                                                                                    returns True
Loop Controls
                           'break' exits the loop prematurely. 'continue' skips the rest of the
                                                                                                    Syntax:
                           current iteration and moves to the next iteration.
                                                                                                           for: # Code to repeat
                                                                                                          if # boolean statement
break
for: # Code to repeat
if # boolean statement
                                                                                                                    continue
                                                                                                    Example 1:
                                                                                                           break
                                                                                                               print(num)
                                                                                                    Example 2:
                                                                                                           for num in range(1, 6):
    if num == 3:
                                                                                                                    continue
                                                                                                               print(num)
```

about:blank 6/10

	3/25, TU:35 PIVI		ibout:blank
			Syntax: not variable
	NOT	Returns `True` if variable is `False`, and vice versa.	Example:
			isLocked = False print(not isLocked)
			returns True if the variable is False (i.e., unlocked).
ŀ			
			Syntax:
			variable1 != variable2
			Example:
			a = 10 b = 20
			b = 20 a != b
	Not Equal(!=)	Checks if two values are not equal.	
			returns True
			Example 2:
			count=0 count != 0
			returns False
L			

about:blank 7/10

9/13/25, 10:35 PM about:blank

```
Syntax:
                                                                                                            object_name = ClassName(arguments)
Object Creation
                           Creates an instance of a class (object) using the class constructor.
                                                                                                     Example:
                                                                                                            person1 = Person("Alice", 25)
                                                                                                     Syntax:
                                                                                                            statement1 or statement2
                                                                                                     Example:
                           Returns 'True' if either statement1 or statement2 (or both) are
                                                                                                            "Farewell Party Invitation"
OR
                                                                                                            grade = 12
if grade == 11 or grade == 12:
    print("Farewell Party Invitation")
                           'True'. Otherwise, returns 'False'.
                                                                                                            else:
                                                                                                                 print("Not eligible")
                                                                                                     returns True
range()
                           Generates a sequence of numbers within a specified range.
                                                                                                     Syntax:
                                                                                                            range(stop)
                                                                                                            range(start, stop)
                                                                                                            range(start, stop, step)
                                                                                                     Example:
                                                                                                            range(5) \#generates a sequence of integers from 0 to 4.
                                                                                                            range(2, 10) #generates a sequence of integers from 2 to 9. range(1, 11, 2) #generates odd integers from 1 to 9.
```

about:blank 8/10

Return Statement	'Return' is a keyword used to send a value back from a function to its caller.	<pre>Example: def add(a, b): return a + b result = add(3, 5)</pre>
Try-Except Block	Tries to execute the code in the try block. If an exception of the specified type occurs, the code in the except block is executed.	<pre>Syntax: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception Example: try: num = int(input("Enter a number: ")) except ValueError: print("Invalid input. Please enter a valid number.")</pre>
Try-Except with Else Block	Code in the 'else' block is executed if no exception occurs in the try block.	<pre>Example: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception else: # Code to execute if no exception occurs Example: try: num = int(input("Enter a number: ")) except ValueError: print("Invalid input. Please enter a valid number") else: print("You entered:", num)</pre>

9/	13/25, 10:35 PM	a	about:blank	
	Try-Except with Finally Block	Code in the `finally` block always executes, regardless of whether an exception occurred.	<pre>Example: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception finally: # Code that always executes Example: try: file = open("data.txt", "r") data = file.read() except FileNotFoundError: print("File not found.") finally: file.close()</pre>	
	While Loop	A 'while' loop repeatedly executes a block of code as long as a specified condition remains 'True'.	<pre>Example: count = 0 while count < 5: print(count) count += 1</pre>
